#### Detailed Description of the Invention

The term "lower alkyl" as used herein means straight and branched chain alkyl radicals containing from one to six carbon atoms, preferably one to four carbon atoms, and includes methyl, ethyl, propyl, 1-methylethyl, butyl, 1,1-dimethylethyl, pentyl and the like, unless stated otherwise.

The term "lower alkenyl" as used herein means straight chain alkenyl radicals containing from two to six carbon atoms and branched chain alkenyl radicals containing three to six carbon atoms and includes ethenyl, 2-methyl-2-propenyl, 4-hexenyl and the like.

- 6 -

The term "lower alkynyl" as used herein means straight chain alkynyl radicals containing from two to six carbon atoms and branched chain alkynyl radicals containing four to six carbon atoms and includes ethynyl, 2-propynyl, 1-methyl-2-propynyl, 3-hexynyl and the like.

5 The term "cyclo(lower)alkyl" as used herein means saturated cyclic hydrocarbon radicals containing from three to six carbon atoms and includes cyclopropyl, cyclobutyl, cyclopentyl and cyclohexyl.

The term "lower alkanol" as used herein means both straight and branched chain alkanols containing from one to four carbon atoms and includes  
10 methanol, ethanol, 1-methylethanol, butanol and the like.

Ther term "inorganic proton acceptor" as used herein means the inorganic bases, preferably the alkali metyl hydroxides, alkoxides, carbonates and bicarbonates, for example, sodium hydroxide, potassium hydroxide, sodium carbonate, sodium bicarbonate, potassium carbonate, sodium hydride, sodium  
15 methoxide and the like.

The compounds of this invention are capable of forming acid addition salts with therapeutically acceptable acids. The acid addition salts are prepared by reacting the base form of the appropriate compound of formula I with one or more equivalents, preferably with an excess, of the appropriate acid in an organic solvent, for example, diethyl ether or an ethanol-diethyl ether mixture.

These salts, when administered to a mammal, possess the same pharmacologic activities as the corresponding bases. For many purposes it is preferable to administer the salts rather than the basic compounds. Suitable acids to form these salts include the common mineral acids, e.g. hydrohalic, sulfuric or phosphoric acid; the organic acids, e.g. maleic, citric or tartaric acid; and acids which are sparingly soluble in body fluids and which impart slow-release properties to their respective salts, e.g. pamoic or tannic acid or carboxymethyl cellulose. The addition salts thus obtained are the functional equivalent of the parent base compound in respect to their therapeutic use. Hence, these addition salts are included within the scope of this invention and are limited only by the requirement that the acids employed in forming the salts be therapeutically acceptable.

The compounds of formula I in which  $R^2$  is oxo or thioxo are also capable of forming addition salts with sodium or potassium. These salts are prepared by reacting the latter compounds of formula I with one or more equivalents of sodium or potassium, or a strong base of sodium or potassium, for example, sodium hydroxide, potassium t-butoxide, sodium hydride and the like. These salts, like the acid addition salts, when administered to a mammal possess the same pharmacological activities as the corresponding nonsalt compound of formula I.

The compounds of formula I or a therapeutically acceptable addition salt thereof are useful as cardiotonic agents for increasing cardiac contractility in a mammal. The cardiotonic effect is demonstrated in standard pharmacological tests, for example, in causing an increase in the contractile force of the isolated cat papillary muscle and reversal of pentobarbital-induced cardiac failure in the dog.

The compounds of formula I of this invention are used alone or in combination with pharmacologically acceptable carriers, the proportion of which is determined by the solubility and chemical nature of the compound, chosen route of administration and standard biological practice. For example, they are administered orally in the form of suspensions or solutions or they may be injected parenterally. For parenteral administration they can be used in the form of a sterile solution containing other solutes, for example, enough saline or glucose to make the solution isotonic.

The tablet compositions contain the active ingredient in admixture with non-toxic pharmaceutical excipients known to be suitable in the manufacture of tablets. Suitable pharmaceutical excipients are, for example, starch, milk sugar, certain types of clay and so forth. The tablets can be uncoated or they can be coated by known techniques so as to delay disintegration and absorption in the gastrointestinal tract and thereby provide a sustained action over a longer period.

The aqueous suspensions of the compounds of formula I contain the active ingredient in admixture with one or more non-toxic pharmaceutical excipients known to be suitable in the manufacture of aqueous suspensions. Suitable excipients are, for example, methylcellulose, sodium alginate, gum acacia, lecithin and so forth. The aqueous suspensions can also contain one or more preservatives, one or more coloring agents, one or more flavoring agents and one or more sweetening agents.

Non-aqueous suspensions can be formulated by suspending the active ingredient in a vegetable oil, for example, arachis oil, olive oil, sesame oil, or coconut oil, or in a mineral oil, for example liquid paraffin, and the suspension may contain a thickening agent, for example beeswax, hard paraffin or cetyl alcohol. These compositions can also contain a sweetening agent, flavoring agent and antioxidant.

The dosage of the compounds of formula I as cardiotonic agents will vary with the form of administration and the particular compound chosen. Furthermore, it will vary with the particular host as well as the age, weight and condition of the host under treatment as well as with the nature and

extent of the symptoms. Generally, treatment is initiated with small dosages substantially less than the optimum dose of the compound. Thereafter, the dosage is increased by small increments until the optimum effect under the circumstances is reached. In general, the compounds of this invention are most desirably administered at a concentration level that will generally  
5 afford effective results without causing any harmful or deleterious side effects. For example, the effective cardiotonic amount of the compounds for oral administration can usually range from about 0.05 to 50 mg per kilogram body weight per day in single or divided doses although as aforementioned variations will occur. However, a dosage level that is in the range of from  
10 about 0.2 to 20 mg per kilogram body weight per day in single or divided doses is employed most desirably for oral administration in order to achieve effective results.

The compounds of formula I also can be used to produce beneficial effects in the treatment of congestive heart failure when combined with  
15 a therapeutically effective amount of another agent commonly used in the treatment of congestive heart failure. Such agents include, for example: vasodilators, i.e. isosorbide dinitrate, captopril, nifedipine, hydralazine and prazosin; diuretics, i.e. hydrochlorothiazide, furosemide and spironolactone; and other cardiotonics, i.e. digitalis and dobutamine. A combination of  
20 the above agents can be substituted for a single agent. Suitable methods of administration, compositions and dosages of the agents are well known in the art; for instance, "Physician Desk Reference", 37 ed., Medical Economics Co., Oradell, N.J., U.S.A., 1983. When used in combination, the compound of formula I is administered as described previously.

(IV)

in which  $R^1$  is as defined above and  $R^3$  is cyano, nitro, methylsulfonyl or aminosulfonyl with an amine V

(V)

in which  $R^4$  to  $R^9$ , m and n are as defined above to obtain the compound corresponding to formula I in which  $R^2$  is oxo and  $R^3$  is cyano, nitro, methylsulfonyl or aminosulfonyl and  $R^1$ ,  $R^4$  to  $R^9$ , m and n are as defined above. The intermediates of formula IV as defined above are also within the scope of this invention.

A second process comprises condensing a compound of formula VI

(VI)

wherein  $R^3$  is cyano, nitro, methylsulfonyl or aminosulfonyl,  $R^4$  to  $R^9$ , m and n are as defined above and  $R^{10}$  is lower alkyl with an amidine of formula II

II

wherein  $R^1$  is as defined above to give a compound of formula I wherein  $R^2$  is oxo,  $R^3$  is cyano, nitro, methylsulfonyl or amino-sulfonyl and  $R^1$ ,  $R^4$  to  $R^9$ ,  $m$  and  $n$  are as defined above.

5 Compounds of formula I wherein X is thioxo may be prepared by reacting a compound of formula VII

(VII)

wherein  $R^1$ ,  $R^4$  to  $R^9$ ,  $m$  and  $n$  are as defined above and  $R^3$  is cyano, nitro, methylsulfonyl or amino-sulfonyl, with an aqueous ethanol solution of potassium hydroxide and hydrogen sulfide. Compounds of formula VII as defined above  
 10 may be reacted with a solution of an inert organic solvent containing an excess of ammonia to give a corresponding compound of formula I wherein  $R^2$  is imino.

Reaction scheme I illustrates a method for preparing the compounds of formula I

Reaction Scheme 1

I in which  $\text{R}^2$  is oxo and  $\text{R}^3$  is cyano, nitro, methylsulfonyl or aminosulfonyl

With reference to reaction scheme 1, the amidine of formula II in which  $\text{R}^1$  is as defined herein is condensed with compound of formula III in which  $\text{R}^3$  is cyano, nitro, methylsulfonyl or aminosulfonyl and  $\text{R}^{10}$  is lower alkyl to obtain the pyrimidine of formula IV in which  $\text{R}^1$  is as defined herein and  $\text{R}^3$  is cyano, nitro, methylsulfonyl or aminosulfonyl according to the method described by S. Kisaki et al., Chem. Pharm. Bull., 22, 2246 (1974). This condensation is preferably achieved by reacting about equimolar amounts of the compounds of formulae II and III in the presence of an inorganic proton acceptor, for example, sodium hydride, sodium alkoxide or potassium carbonate, in an inert organic solvent, for example, ethanol or dimethylformamide, at about 20 to 90° C for about two to ten hours.

5

some of the compounds of formula I

### Reaction Scheme 2

30

With reference to reaction scheme 2, the compound of formula III in which R<sup>3</sup> is cyano, nitro, methylsulfonyl or aminosulfonyl and R<sup>10</sup> is lower alkyl is reacted with the amine of formula V in which R<sup>4</sup> to R<sup>9</sup>, m and n are as defined herein to obtain the corresponding compound of formula VI in which R<sup>3</sup> is cyano, 5 nitro, methylsulfonyl or aminosulfonyl and R<sup>4</sup> to R<sup>10</sup>, m and n are as defined herein. For this reaction, preferably about equimolar amounts of the compounds of formulae III and V are allowed to react at about 20 to 40°C for about ten minutes to two hours in an inert organic solvent, preferably dimethoxyethane, and the compound of formula VI is isolated.

10        Condensation of the compound of formula VI in which R<sup>3</sup> is cyano, nitro, methylsulfonyl or aminosulfonyl and R<sup>4</sup> to R<sup>10</sup>, m and n are as defined herein with the amidine of formula II in which R<sup>1</sup> is as defined herein gives the corresponding compound of formula I in which R<sup>2</sup> is oxo; R<sup>3</sup> is cyano, nitro, methylsulfonyl or aminosulfonyl; and R<sup>1</sup>, R<sup>4</sup> to R<sup>9</sup>, m and n are as defined 15 herein. When conducting this condensation, preferably about equal molar amounts of the compounds of formula II and VI are condensed at about 75 to 150°C for about 20 to 30 hours in an inert organic solvent, preferably dimethylformamide.

To convert the compound of formula I in which R<sup>2</sup> is oxo to the 20 corresponding compound of formula I in which R<sup>2</sup> is thioxo, the following chemical reactions are required. In the first step, the sodium salt of the compound of formula I in which R<sup>2</sup> is oxo is reacted with an excess of phosphorous oxychloride at about 90 to 120°C for about one to five hours to obtain the corresponding 4-chloropyrimidine derivative. Treatment of the latter 25 derivative with a solution of water and ethanol containing an excess of potassium hydroxide and hydrogen sulfide at about 20 to 40°C for about 20 to 30 hours gives the corresponding compound of formula I in which R<sup>2</sup> is thioxo; R<sup>3</sup> is cyano, nitro, methylsulfonyl or aminosulfonyl; and R<sup>1</sup>, R<sup>4</sup> to R<sup>9</sup>, m and n are as defined herein.

30        Treatment of the above 4-chloropyrimidine with a solution of an inert organic solvent, preferably a lower alkanol, containing an excess of ammonia at about 50 to 80°C for about 20 to 30 hours gives the corresponding

compound of formula I in which  $R^2$  is imino;  $R^3$  is cyano, nitro, methylsulfonyl or aminosulfonyl; and  $R^1$ ,  $R^4$  to  $R^9$ , m and n are as defined herein.

Hydrolysis of the compound of formula I in which  $R^3$  is cyano; and  $R^1$ ,  $R^2$ ,  $R^4$  to  $R^9$ , m and n are as defined herein, preferably with sulfuric acid at about 60 to 100° C for one to ten hours, gives the corresponding compound of formula I in which  $R^3$  is aminocarbonyl; and  $R^1$ ,  $R^2$ ,  $R^4$  to  $R^9$ , m and n are as defined herein.

The following examples illustrate the preparation of compounds of this invention.

## Test for Cardiotonic Activity in Isolated Cat Papillary Muscle

A cat of either sex was anesthetized with Na pentobarbital, 25-30 mg/kg i.v. The heart was rapidly removed and placed in cool Tyrode's solution which had been equilibrated with 95% O<sub>2</sub>-5% CO<sub>2</sub>. The right ventricle was opened by cutting down the sides and around the apex so that the free wall could be folded back on the atrioventricular groove. Usually at least three suitably-sized papillary muscles were found (1 mm or less in thickness). Threads were tied around the chordae tendoneae and the base of the muscle just above its point of insertion into the ventricular wall. The chordae were cut, and the muscle was removed along with a small button of ventricular wall. If a sufficient number of papillary muscles were not present, trabeculae carneae could also be used. The best ones were usually found inserting just under the valve.

The preparations were mounted in tissue baths containing Tyrode's solution at 37°C bubbled with 95% O<sub>2</sub>-5% CO<sub>2</sub>. One thread was affixed to a tissue holder incorporating a pair of platinum electrodes and the other thread was attached to a force displacement transducer. Initial tension placed on the preparation was 0.2 g (less for very small muscles). The preparations were stimulated with square-wave pulses, 2-4 msec. in duration and 10% above threshold voltage, at a rate of 0.5Hz. The muscles were then gently and gradually stretched to their optimum force-length relation (at which twitch tension was maximal-further stretching did not result in any further increase in the overall magnitude of the twitch). The preparations were then allowed to equilibrate for one hour with frequent changes of the bathing fluid (10-15 min intervals). The test compound was added to the bath in 0.1 mL of vehicle and incubated with the preparation for 15 min or until peak effect was attained.

Using this method, the following representative compounds of formula I were effective for increasing the force of contraction of the papillary muscle (the amount of test compound in the bath and increase in contractility is given in the parenthesis): 1,4-dihydro-2-methyl-4-oxo-6-[(3-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile (at 10<sup>-4</sup> molar increased contractility by 98%), 1,4-dihydro-2-methyl-4-oxo-6-[(4-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile

(at  $10^{-4}$  molar increased contractility by 139%), 1,4-dihydro-2-methyl-4-oxo-6-[(phenylethyl)amino]-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 142%), 1,4-dihydro-2-ethyl-4-oxo-6-[(3-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 140%), 1,4-dihydro-6-[(2-furanylmethyl)amino]-2-methyl-4-oxo-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 108%, 2-cyclopropyl-1,4-dihydro-4-oxo-6-[(3-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 129%), 1,4-dihydro-2-methyl-6-[(2-(4-morpholinyl)ethyl)amino]-4-oxo-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 62%),  
10 1,4-dihydro-2-methyl-4-oxo-6-[[2-(3-thienyl)ethyl]amino]-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 149%), 1,4-dihydro-2-methyl-4-oxo-6-[(2-propenyl)amino]-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 61%) and 1,4-dihydro-6-(ethylamino)-2-methyl-4-oxo-5-pyrimidinecarbonitrile (at  $10^{-4}$  molar increased contractility by 88%).

## Pentobarbital-induced Cardiac Failure in the Dog

A dog of either sex was anesthetized with Na pentobarbital, 30-35 mg/kg i.v. The trachea was intubated and the animal was respired at a rate of 20 breaths/min (stroke volume = 15 cc/kg). Both femoral veins were cannulated.  
20 One cannula was used for infusion of pentobarbital to induce and maintain failure, the other for injection of test compounds. A cannula was inserted into the aorta via a femoral artery and the cannula was attached to a blood pressure transducer for measurement of systolic, diastolic and mean aortic blood pressure. A Millar pressure-tip catheter was inserted into the other femoral  
25 artery and advanced into the left ventricle to record intraventricular pressure and  $dP/dt$ . Subdermal needle electrodes were used to record a lead II electrocardiogram and heart rate.

Following a stabilization period of at least 30 min, experimental failure was induced by the i.v. infusion of Na pentobarbital, 0.75 mg/kg/min in 0.2 mL of  
30 saline/min, until a 40-50% decrease in peak positive  $dP/dt$  was obtained. The failure state was maintained at this level throughout the experiment by continuous infusion of Na pentobarbital, 0.11-0.15 mg/kg/min. Once the maintenance infusion was started, at least 15 min were allowed to elapse before test drugs were administered.

Test compounds were prepared in N saline. Increasingly higher doses were given i.v. at 30 min-1hr intervals in order to determine a therapeutic (50% increase in  $dP/dt$ ) to toxic (appearance of arrhythmias) ratio where possible.

Using this method, the following representative compounds of formula I 5 were effective for increasing the cardiac contractility of the heart (the amount of test compound in mg per kg of body weight administered i.v. to give a 50% increase in  $dP/dt$  is given in the parenthesis): 1,4-dihydro-2-methyl-4-oxo-6-[(3-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile (0.06 mg/kg), 1,4-dihydro-2-methyl-4-oxo-6-[(4-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile (0.07 10 mg/kg), 1,4-dihydro-2-ethyl-4-oxo-6-[(3-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile (0.05 mg/kg), 1,4-dihydro-6-[(2-furanylmethyl)amino]-2-methyl-4-oxo-5-pyrimidinecarbonitrile (0.06 mg/kg), 2-cyclopropyl-1,4-dihydro-4-oxo-6-[(3-pyridinylmethyl)amino]-5-pyrimidinecarbonitrile (0.02 mg/kg), 1,4-dihydro-2-methyl-4-oxo-6-[[2-(3-thienyl)ethyl]amino]-5-pyrimidinecarbonitrile 15 (0.08 mg/kg), and 1,4-dihydro-6-(ethylamino)-2-methyl-4-oxo-5-pyrimidinecarbonitrile (0.02 mg/kg).
